Global-COE Frontier Seminar

Rheology of serpentines, seismicity and mass transfer in subduction zone

Speaker : Dr. Buruno Reynard
Affiliation : CNRS Ecole Normale Superieure de Lyon
Date & Time : 13:30 - 14:30 on Monday, June 15, 2009
Place : Earth Science Bldg. 2F #201 Lecture Room
Contact : Associate Prof. Motohiko Murakami
TEL: EXT#5789 / E-mail: motohiko@m.tains.tohoku.ac.jp

Abstract:

Serpentinites have a lower density and lower viscosity than "dry" ultramafic rocks and it was proposed, based on numerical simulations, that they play a major role in mantle-slab decoupling, and in downward (sink) or upward (exhumation) motion of eclogites and ultra-high pressure (UHP) rocks in subduction zones. Rheological data on antigorite, the stable variety of serpentine in subduction zones, were obtained over a P-T range of 1-4 GPa and 200-500 /deg C that cover most of its stability field. The results confirm that serpentinites acts as a weak layer that allows significant mass transfer along the "serpentinized channel" and dynamic processes such as mantle slab decoupling, and mantle wedge convection. Regardless of the temperature, serpentinized mantle at the slab surface has a low viscosity that allows localizing the deformation and impeding stress build-up. It will limit the downdip propagation of large earthquakes, and allow viscous relaxation as an origin of post-seismic deformations and slow earthquakes. Models of growth and transport of a serpentinized channel using available kinetic and present rheological data explain high exhumation rates of eclogites and limited thickness of the channel at great depths (\( \equiv 50 \) km), and slower exhumation in a thick hydrated mantle corner at shallower depths. Such channels may be difficult to detect from seismic tomography or using guided waves because of their small thickness (<2-3 km).
